Acknowledgments

The author would like to thank all the people whose helpful comments and practical assistance have been incorporated into this project; in particular, Charlie Rook of the Victorian Office of Corrections for his enthusiastic commitment and his genius at finding data. Other key supporters have included Andrew MacNeil (Victoria Police), Bill Johnston (Law Department), Ivan Beringer and Malcolm Feiner (Office of Corrections) and John King (Australian Bureau of Statistics, Victoria), and members of the Demography Department of the Australian National University. It would also be unfair to forget typists Marjorie Johnson, Trish Psaila and Evelyn Jacobsen who, after umpteen redrafts, can probably recite the whole text from memory.

Thanks are also due to the Victorian Department of Community Welfare Services, the Office of Corrections and Neilson Associates for permission to include the data and examples which form the bulk of this publication and which were originally taken from my work for the Corrections Master Plan of December 1983.

J. Walker

Foreword

The Australian legal and penal system, despite the unfortunate impression it sometimes gives, via the media, to the public, is constantly changing and reacting to new developments. For example, the Australian police forces have had to cope with increases of something like 300 per cent in certain categories of reported assaults,* 600 per cent in robberies and 400 per cent in break-and-enters over the last 20 years, not to mention traffic offences of which several new species have been made law in that time. Similar proportionate increases have taken place in the numbers of court hearings and charges heard in the same period. Penal institutions have taken their share of the 'output' of these proceedings, and, even with increasing use of non-custodial penalties, prisons have catered for something like a 40 per cent growth in daily average numbers of prisoners. Furthermore, largely because prisons are so labour-intensive, the average cost per prisoner has risen by something like 250 per cent in real terms during the same period, even though by and large we have reduced the capital component of these costs by cramming more prisoners into the same increasingly crowded and outdated prisons.

Much of the increase in these numbers is due to growing population, so that, with an increasing tax-base, the community has been able to provide for commensurate increases in the numbers of police, judicial officers and correctional facilities. However, as in other Western countries, our correctional administrations are currently under particular pressure as prisoner numbers grow in spite of strenuous efforts to divert offenders to non-custodial forms of punishment. 'Demand' for prison accommodation has almost everywhere outstripped supply, but because of the economic and financial constraints applying to state governments at this time there is great reluctance to commit the funding required to construct more accommodation without considerable study of the whole range of options.

This monograph is designed to assist in the identification of future trends in prisoner numbers, both in the presence and absence of diversionary policies such as community-based corrections or prisoner early-release schemes. The selection of policy mixes appropriate to particular circumstances depends on relative costs and degrees of public acceptance of the policy options, and these in turn depend on the circumstances and precise

* These figures are based on tables in Source Book of Australian Criminal & Social Statistics 1900-1980, Satyanshu K. Mukherjee, Evelyn N. Jacobsen and John R. Walker, Canberra: Australian Institute of Criminology, 1981.

details of the policies themselves, so only the analytical techniques, with appropriate examples, can be shown here. The reader should not infer any recommendations in relation to the actual policies discussed. It is intended, however, to show how policy options can be compared with a view to determining the most appropriate options, particularly in a public climate in which the costs of imprisonment are seen as an undesirable burden on the taxpayer while the alternatives to imprisonment are sometimes seen as inadequately protecting that same law-abiding taxpayer.

Part One consists of a discussion, with examples from Victoria, of the statistical relationships between the demographic structure of the general population and the composition of the 'clientele' of the justice and penal systems. Evidence is produced in support of the contention that these relationships are sufficiently stable over time to be used in projecting future client numbers. Part Two is a very brief discussion of the types of model which have traditionally been used in this area of forecasting, and a summary of the sequential structure of the model eventually developed for forecasting the Victorian corrections population. Part Three discusses how these types of models should be used and presents examples of the range of outputs obtained in the Victorian case.

PART I

THE KEY FEATURES OF A CORRECTIONS FORECASTING MODEL

Introduction

This is a subject which has only recently become a public issue, not only in Australia but also in the United States, where much effort has been directed to producing reliable forecasting models since rapid increases in prison populations made the construction of additional facilities necessary.

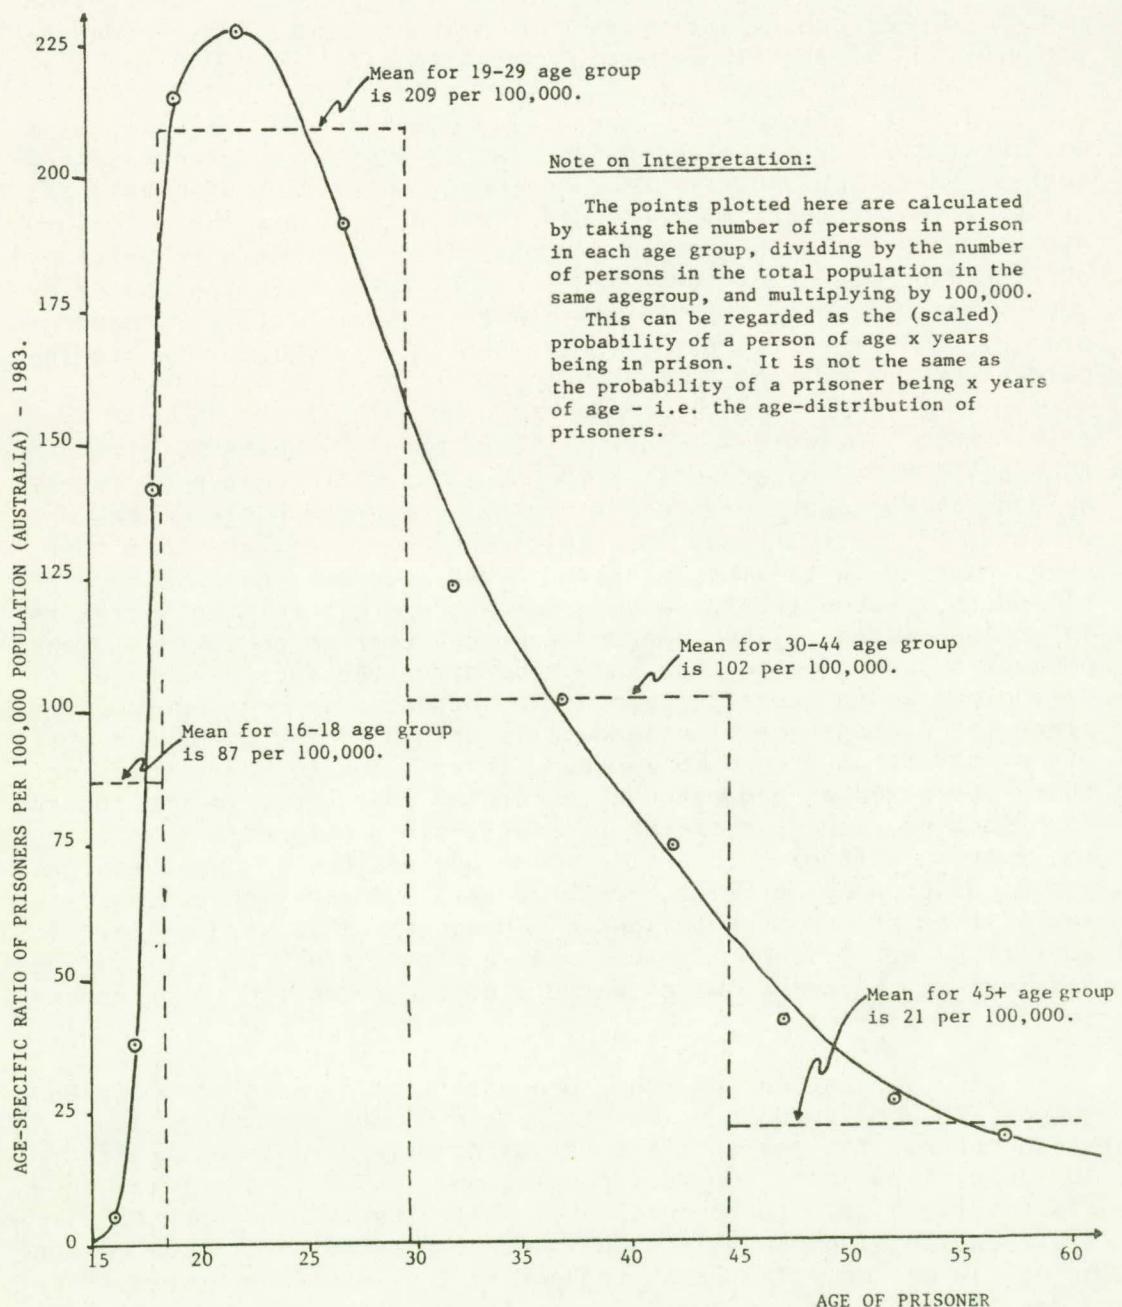

Initial attempts at forecasting prisoner numbers were based on simple trend extrapolation, and failed miserably as crime rates soared above previously known values. On reading of escalating crime rates, members of the public, politicians and the judiciary all tended to demand greater punishment for offenders, completely overlooking the fact that much of the escalation was caused by juveniles for whom custodial sentences were entirely inappropriate, but the resulting longer sentences added further to the burdens on the prisons.

More enlightened analysts in both the United States and Australia have observed that two world wars coming approximately a generation apart produced a highly pronounced bulge in the age pyramid of virtually all participating countries, and that this, when coupled with the highly skewed age/sex distribution of offenders, accounted for a very large proportion of the increases in crime rates. The same observation, carried on to the prison population, suggested that some time after the increased rates of offending would come commensurate increases in prisoner numbers since the average age of offenders is around 19 years whereas that of prisoners is around 29 years.² This is due to the simple fact that there is an understandable lack of enthusiasm in the courts for sending young, particularly first-time, offenders to prison, so that an offending cohort of young persons has to spend several years developing criminal records before their numbers begin to swell the prison populations. However, this lag effect is amplified as prisoner numbers also stay high long after the passing of the crime 'wave' because of the retention of prisoners serving long terms.

An indication of the propensity of persons of given age groups to be serving prison terms can be obtained from Figure 1 which shows the age-specific ratios of prisoners in Australia on 30 June 1983 per 100,000 population. This is not the age-distribution of prisoners, but effectively the probability distribution of persons from the general population of a given age being in prison. The graph shows very low imprisonment rates for under 18 year olds and over 45 year olds, medium rates for 18 year olds and 30-44 year olds and very high rates for 19-29 year olds. Clearly, when the 19-29 age group is a significant proportion of the general community a high prison population should be expected, if this graph is consistent over time.

This figure itself suggests a very simple forecasting model

Figure 1

AGE-SPECIFIC RATIOS OF PRISONERS PER 100,000 POPULATION
BY AGE - AUSTRALIA 1983

Australian Institute of Criminology, Canberra, 1984.

for prisoner numbers. One could obtain forecasts of the number of persons in the general population in the 16-18, 19-29, 30-44 and 45+ age groups and multiply these figures by the means suggested in the graph, that is, 87, 209, 102 and 21 per 100,000 respectively. This model, however, could not take account of changes in any factor other than population change and would therefore be of little practical value since a wide range of policing, legislative and penal policies can clearly also affect imprisonment rates, particularly in the medium-long term. Furthermore, for the same reasons, even if similar models were constructed for non-custodial sentences, based on age-specific rates, the combined models could not adequately assist the evaluation of these alternative forms of adult correction.

Adult corrections forecasting models therefore must incorporate at least four observed features of the demography, crime and justice fields if they are to be capable of adequately describing the system by which people come to serve corrective sentences:

- * The number of persons in each age/sex group in the general population is reasonably predictable five, ten or even 20 years into the future so long as migration remains within expected bounds.
- * The proportion of persons in each age/sex group in the general population which will be proceeded against for a given offence-type is reasonably stable over time, but may be modified by changes in the law, in social attitudes or in socio-economic conditions.
- * The severity and nature of sentences handed down for a given offence-type are stable over time, but may be modified by legislation or by judicial practice.
- * The rules governing parole and remission are stable over time, but may be modified by legislation or by the changing practices of corrections administrators or parole boards.

These four features are dealt with in detail below.

Forecasting the Future Age/Sex Distribution of the Population

Although there have been cases of demographic forecasting being woefully inaccurate in the long term, techniques developed since the 1950s have made it feasible not only to produce reliable projections of total populations, based on fairly sophisticated assumptions about trends in births, deaths and migration, but also to produce far more detailed projections of, for example, labour forces, rural and urban population, school enrolments and households.³ Such forecasts are generally built upon age and sex specific forecasts of population combined with knowledge of age/sex specific participation rates in the labour force, school or household formation. Improved knowledge of inter-relationships between population and economic and social factors has resulted in greater confidence in the results of these models and, particularly in developed countries such as Australia, the basic parameters are so stable (for example, birth rates, death rates)

that forecasting population even at a detailed age/sex disaggregated level has become largely a problem of forecasting the composition of migration flows. To some extent, of course, these are government controlled so that even this problem is reduced to manageable proportions.

For some years the Australian Bureau of Statistics has been developing population forecasting models for Australia⁴ and its component states and territories. They provide several sets of projections based on differing assumptions about fertility, mortality and migration. For example, the alternative fertility assumptions used in the four basic ABS models are:

Total Fertility to increase from 1936 per 1000 women in 1981 to 3020 by 1985 and to decline to a low of 1900 by 1987, remaining constant at 1900 to the year 2021.

OR

Total Fertility to gradually increase from 1936 per 1000 women in 1981 to a long term replacement level of 2110 in 1987, remaining constant thereafter.

Mortality is assumed to continue its slow decline, giving life expectations at birth of 72.25 and 73.42 years for males in 1985 and 2020 compared with a 1981 figure of 71.38 years. The corresponding values for females are 78.42 years in 1981, 79.58 in 1985 and 82.64 in 2020. No alternative assumptions are given.

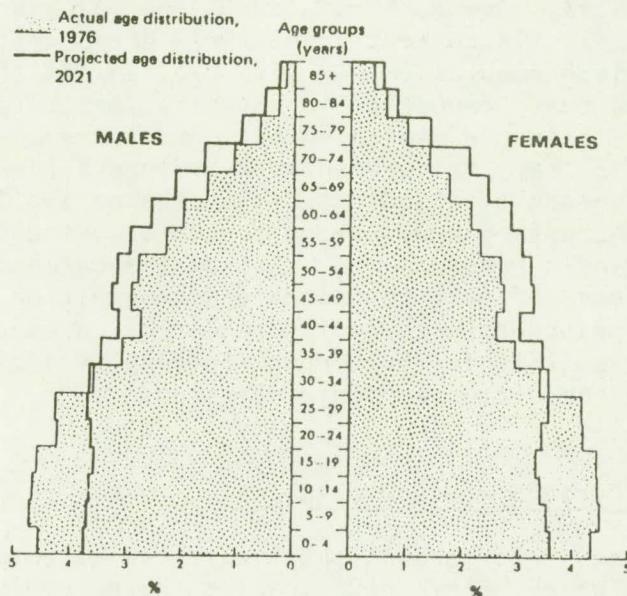

Migration alternatives are: 75,000 or 125,000 persons net per year.

The difference between the maximum and minimum total population figures for Australia under these projections is of the order of 8 per cent at year 2000 and 17 per cent in the year 2020. Since government planning policies are generally geared to the relatively shorter end of this scale the likely range of error in corrections planning, resulting from incorrect population growth assumptions, will be small. However, even an 8 per cent increase in population expectations would imply around 800 extra prisoners to be housed in Australia.

It is generally expected that Australia's population, having experienced a post-war baby boom in the late 1940s/early 1950s and a significant immigration movement in the post-war period, will 'age' considerably in the next few decades, that is, the proportion in the 45+ age group will increase.⁵ Figure 2 shows age-pyramids for Australia in 1976 and (projected) 2021 and clearly outlines the shift in population this will entail. Paradoxically with the reduction in the numbers in the crime-prone juvenile and young adult age groups and the increase in the elderly, we are likely to be faced on the one hand with reducing actual crime levels and on the other an increased public consciousness and fear of victimisation. This speculation is however not the subject of this monograph.

Figure 2

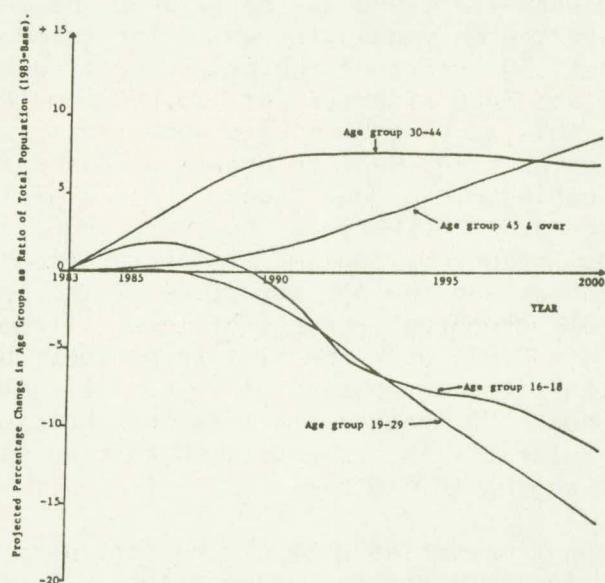

POPULATION PYRAMID SHOWING THE AGE AND SEX DISTRIBUTION OF AUSTRALIA AS AT 30 JUNE 1976 AND THE PROJECTED POPULATION AS AT 30 JUNE 2021 ASSUMING 50,000 IMMIGRANTS PER ANNUM

produced its own population projections in 1982⁶ based on the ABS method, and these graphically show how the key age groups are expected to vary in the next two decades. Percentage changes from the 1983 population structure are shown in Figure 3 in the same age groupings as used in our simple prisoner forecasting model earlier, that is, 16-18, 19-29, 30-44 and 45+ years of age. As shown earlier it is currently the 19-29 group which contributes most to the prison population, so Victoria can, on the fact of it, expect an eventual reduction in potential prison populations of about 16 per cent in per capita terms. (Of course, with a growing population this may still mean more prisoners than at present.) However, the graph also indicates that the period 1983-1987 will be one of increasing pressure on prison accommodation and since there is already pressure on that accommodation in 1983 it is clear that some effort to increase accommodation and/or reduce throughput of prisoners is urgently required. Subsequent sections of this monograph will follow through the analysis of the range of options facing the Victorian administration.

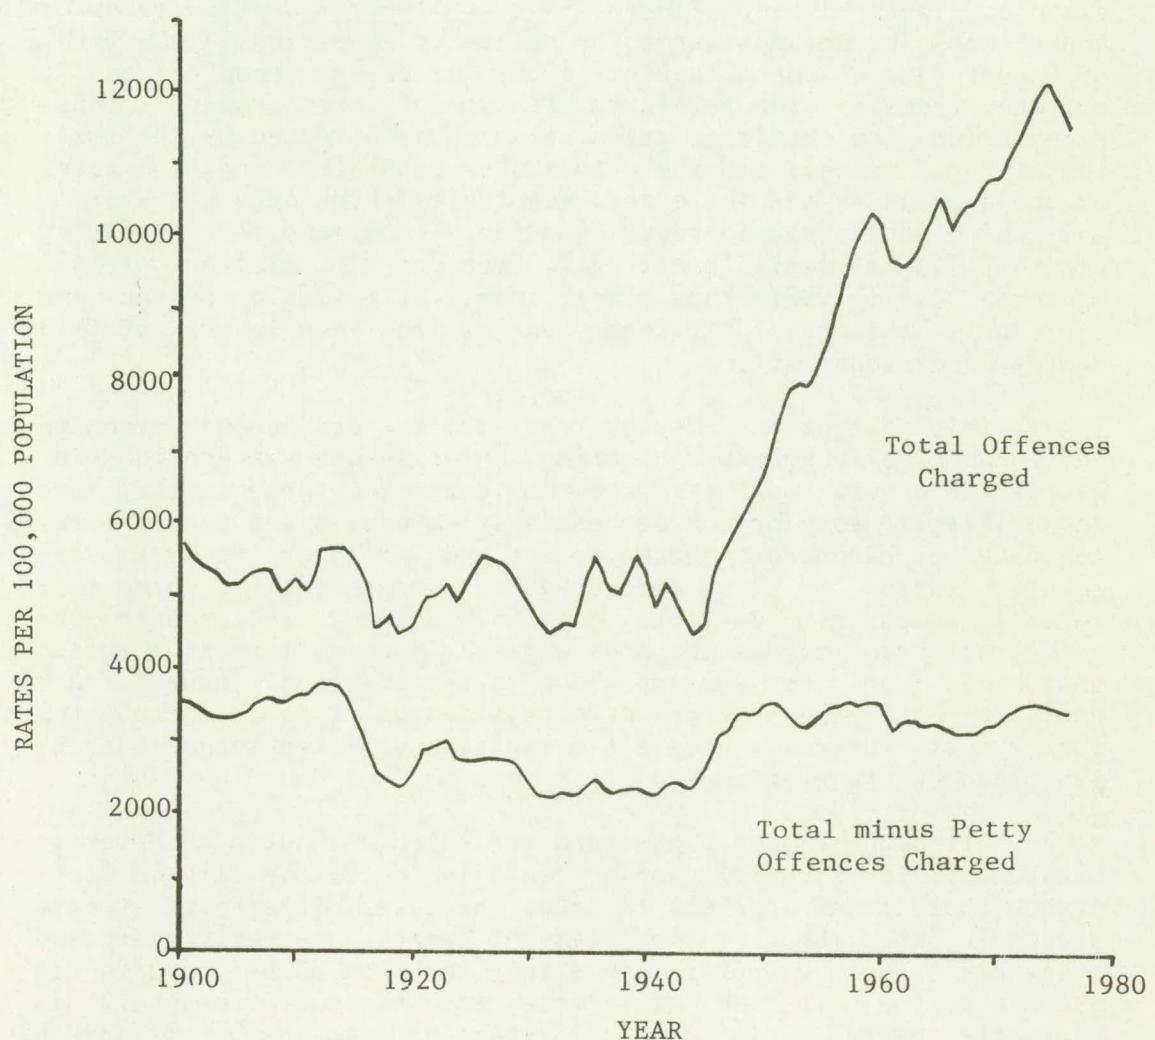

The Number of Persons Proceeded Against

Mukherjee⁷ has shown that, with the exception of traffic offences, of which many new species have evolved during the period, per capita crime rates in Australia have hardly varied during the whole of the twentieth century particularly when age and sex are taken into account. Figure 4 shows the volume of offences charged before Magistrates' Courts per 100,000 population aged 10 years and over for Australia between 1900 and 1976. The graph also shows the trend resulting if 'petty' offences (almost entirely made up of traffic offences) are taken out. This trend shows variation between around 2000 and 4000. However, as Mukherjee shows, the exceptional years between 1915 and 1945, covering two world wars and the Great Depression, account for most of the years when the trend was below 3000 and the early years of the century are the only ones for which the trend rose above 3500. Over the last 30 years of the graph the figure fluctuates only between 3000 and 3500 offences per 100,000 population aged 10 and over. Since this curve effectively represents these offences for which persons may be sent to prison we can already derive some reason for optimism in our search for a basis of forecasting prisoner numbers. Mukherjee, however, goes further into the realms of demography by looking at the relationships between the number of offences and the age structure of the population. Using a simple purely demographic model of total offences he obtained a correlation of 0.97 over the 77 year period. Unfortunately the key variables (total population aged 10 and over and the percentage under 10 years) are less than helpful and there is a hint of circularity in the model. Mukherjee is forced to leave the question hanging in mid air.

Although time-series data of the sort used in Crime Trends⁸ is useful to indicate general associations between variables, far more complex statistics are required to establish correlations of the type required for forecasting prisoner numbers. In particular, we know intrinsically that offence type and age and sex of

Figure 4

VOLUME OF OFFENCES CHARGED BEFORE MAGISTRATES' COURTS PER
100,000 POPULATION AGED 10 YEARS AND OVER:
AUSTRALIA 1900-1976

Source: Mukherjee, S.K., Crime Trends in Twentieth-Century Australia, George Allen & Unwin/Australian Institute of Criminology, 1981.

offender are important indicators of whether a person is likely to commit offences,⁹ but time-series data at this degree of disaggregation is difficult to obtain. Fortunately, even when we look at a single year's data for one jurisdiction, we find that distributions by age and offence type are generally so smooth across the age ranges that they are convincing testimony to the stability (at least in the short term) of the relationships revealed. For example, Table 1 and Figure 5 show the comparative rates of appearances by persons warned by police or appearing in any level of court in Victoria during 1980, by 22 age groupings and 16 offence types. The striking feature of these graphs is that, except for the homicide category which is affected by the small number of offences, all the graphs show smoothly increasing rates of appearances as age increases, eventually reaching a peak, at an age which varies considerably by offence type, and then declining smoothly to a negligible level. Five years of similar data for Victoria (1976-1980) show almost identical trends by offence and age - only the homicide category varies from year to year at this degree of disaggregation.

This exception must be treated with care because although the number of persons appearing in any one year on homicide charges is a very small percentage of total court cases, they face comparatively long prison sentences if convicted and tend thereby to make a disproportionate impact on prisoner numbers. The solution used in this model was to average out the three most recent years of available data, 1978-1980, and smooth the resulting trend across the age ranges. Since no intuitive reason could be found for any age group to simultaneously have a lower homicide rate than the groups both sides of it in the graph, the curve must logically have a similar single peaked shape to those exhibited by other offences.

Although Figure 5 has been presented without a male/female breakdown, for simplicity of presentation only, the data in Table 1 show that it is important to treat the sexes differently at this stage in the model. For reasons which are well discussed elsewhere¹⁰ women do not commit either the same number of offences as men or the same types of offences with the same frequency. In virtually every jurisdiction in the world the number of female prisoners is far less than the number of males. Any prisoner forecasting model must therefore take account of this at the appropriate stages in computation.

Although Victorian offender data have been presented in this discussion of the model, and one could as a first order approximation assume it applies to other States, it is a relatively simple matter to obtain and replace it by similar data from other jurisdictions. Indeed, if projections are required for another jurisdiction it is probably advisable to do so, since although radically different patterns of criminal behaviour are unlikely to occur between jurisdictions, it may well be true that reporting, policing, legislative or penal differences occur which affect the various parameters of the model.

Figure 5

COMPARATIVE RATES* (PER 100,000 PERSONS) OF APPEARANCES BY PERSONS WARNED BY POLICE OR APPEARING IN ANY LEVEL OF COURT BY MOST SERIOUS OFFENCE AND AGE - VICTORIA 1980

Note: These graphs are scaled so that the tallest 'bar' represents the age group whose rate per 100,000 persons is highest for that offence, e.g. the age group with the highest rate of appearance on Homicide charges is the 21-24 years age group, while 16 year olds have the highest rates for Sex Assaults, Other Theft and Total Offences.

Source: Australian Bureau of Statistics, Number of Appearances by Most Serious Offence by Sex and Result of Hearing, Supreme Court Cases, 1976-1980, Number of Appearances by Most Serious Offence by Sex and Result of Hearing, County Court Cases, 1976-1980, Number of Appearances by Most Serious Offence by Sex and Result of Hearing, Magistrates' Court Cases, 1976-1980, and Number of Appearances by Most Serious Offence by Sex and Result of Hearing, Children's Court Cases, 1976-1980, all published Melbourne, 1983.

The Disposition of Convicted Persons

Courts are subject to such a range of case-law and legislated constraints in imposing sentence, that percentage distributions across the range of offence-types must be relatively constant over time, except where deliberate variations are made in reaction to changing social and political circumstances. Only the value of fines imposed would be expected to vary systematically over time, because of inflation, and in this area the legal limits are adjusted from time to time to reflect this fact of life. Figure 6 and Table 2 show the proportions of the various disposition-types for Victoria 1980, from the same ABS source, and examination of trends indicate that these proportions have been stable at least since 1976 when statistics of this type were first available.¹¹

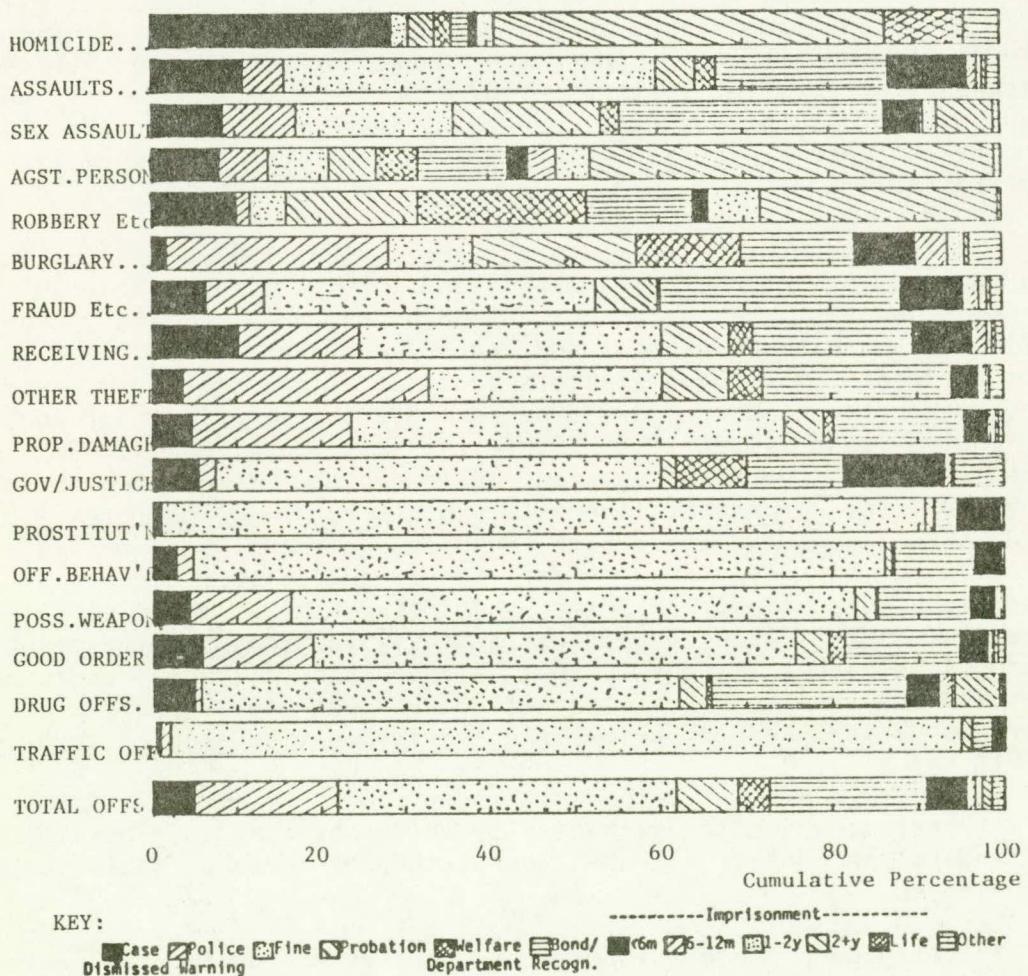

It is interesting at this stage to see if some insight can be gained by comparing Figures 5 and 6. The offences for which prison is the most frequent disposition are homicide, other offences against the person, and robbery and extortion. These are all offences involving threats or actual violence to the person and, other than robbery, are offences more characteristic of adult offenders than juveniles. Other offences where imprisonment is used to any appreciable extent (offences against government and justice, the property offences of burglary, fraud and receiving, and even the drug offences) tend to dispose a far higher proportion of convicted offenders to non-custodial sentences such as probation, fines or police warnings. Some of these offences are far more likely to be committed by juveniles, and the graphs (and commonsense) suggest that either the offence has to be particularly serious or the offender must have a particularly serious prior record before the imprisonment penalty is used in their cases.

Here then is the mechanism by which the age-distribution of offenders is not at all the same as that of persons liable to be imprisoned.

Although these proportions were stable during the period 1976-80, it is interesting to select some examples of how significant changes may occur over time which could have major effects on prisoner numbers. In the legislative area, maximum penalties for the Federal offences of importation and possession of illegal (drug) imports were doubled in 1978, making imprisonment more likely to be administered in these offences, and resulting in much longer terms in gaol than under the previous guidelines. Proposed 'decriminalisation' of prostitution might well result in a reduction of the numbers sent to prison for these offences. A different type of example, but one of quite major importance in terms of sheer numbers of prisoners, is that of the fine defaulter, that is, someone originally fined but being unable, or preferring not, to pay the fine. These persons presently serve short prison sentences, averaging 23 days in Victoria, and currently account for around 0.4 per cent of all persons fined. (Persons serving out fines while also in prison on other charges are not included in these figures as this extension

of time served is assumed to be taken account of in terms of the effective sentences of persons serving short (under 1 year) sentences.¹²⁾ Fine defaulters currently account for almost 40 per cent of all prison receptions in some Australian jurisdictions and proposals are being considered to divert them from prison to Community Service Orders, in which they repay their 'debt' to society in terms of their own time and effort rather than in a monetary penalty, which many may genuinely not be able to afford to pay. Each of these examples would clearly have the potential to affect prison populations, and it is therefore essential to include mechanisms for simulating their effects in any prisoner forecasting model.

We must also consider whether sex plays a role in the disposition of persons charged, since it clearly is significant in determining the number of persons charged. The courts are supposed to act on the circumstances of the offence and of the offender, but is the sex of the offender a fact which should affect the disposition of the case? The data confirm that sex does affect the number of persons going to prison since, if one applies the percentages from Table 2 to the number of females appearing in court in one year, a result is obtained which is considerably in excess of actual female receptions into prison per year. This may in fact constitute evidence of bias but it more likely represents the facts that women commit less serious offences than men and are less likely to continue offending after apprehension. (See Table 3 which shows the percentages of offenders who were previously known to police in 1979, by age, sex and offence category.)

These differences between the sexes suggest that if it is important to know the sex breakdown of future prisoner numbers then a model should be used which differentiates at the disposition stage. For the sake of simplicity, however, subsequent sections of this discussion will use a single set of disposition percentages, producing estimates of the number of persons, not by sex, committed to imprisonment. If necessary, however, all jurisdictions should be able to provide the relevant disposition data by sex which would enable separate estimation of male and female prisoner numbers.

The Determination of Time Actually Served in Prison

Prisoner numbers on hand at a given time depend not only on the numbers of prisoners sentenced by the courts, and their sentence lengths, but also on the system which determines their release dates. All Australian prison systems have adopted the concepts of parole and remissions although the details differ from jurisdiction to jurisdiction and, indeed, from time to time. The rules vary according to the length of head sentence and whether the judge or magistrate himself set minimum terms. However, it would be reasonable to say that regulations and practice combine to produce a generally stable and predictable pattern of relationships between head sentences and time actually served in prison, even though this may be intentionally changed, as for example in both New South Wales and Victoria in 1983 and 1984.

Table 4 uses Victorian data and shows the distribution of effective minimum terms currently served by prisoners in Victoria and their relationships to head sentences.¹³ Reading down the columns, for example, it shows that, of those sentenced to (a maximum) between four and five years, 25 per cent will be either specifically given a minimum term of 1-2 years by the court, or if no minimum sentence was handed down will be granted by the Parole Board a release date equivalent to such a minimum term. Forty per cent of prisoners with 4-5 year head sentences will receive effective minimum terms of 2-3 years; 25 per cent will receive 3-4 years and only 10 per cent will serve the full 4-5 years.

The data required to construct a matrix of this form is normally readily available from prison records so once again it is a relatively simple matter to build a model appropriate to any jurisdiction.

To determine the actual time to be spent occupying a prison bed one has now to subtract time earned for good behaviour. In Victoria for example remissions are earned through time actually served at the rate of one month for every two served, so that a prisoner with an eight year head sentence and a minimum term of six years can normally expect to leave prison on parole after serving four years of his sentence if he receives full remission. The number of prisoners who do not receive full remission is small and the amount of remission lost is also small in relation to the overall time served. The model need not therefore make allowances for lost remissions.

Table 4

DISTRIBUTION OF EFFECTIVE SENTENCE (BEFORE REMISSIONS)
GIVEN HEAD SENTENCE - VICTORIA 1982

Source: Parole and Remissions, Second Report of the Sentencing Alternatives Committee of Victoria, Law Department, Melbourne, 1982.

One area in which the model has to be particularly sensitive, because of the large numbers of prisoners involved, is in the shorter sentences. The distribution of sentences handed down by the courts is highly skewed toward sentences of two years and less. Currently around two-thirds of prisoners serving gaol sentences will be free in under two years and more than half of them will be out in less than one year. Because of their large numbers these short-term prisoners have the potential to influence total prisoner numbers both quickly and significantly. In a forecasting model which works on a year-by-year basis it is essential to accurately model the flow of these prisoners. The number of prisoners sentenced during the year to terms of less than one year is a large proportion of total persons sent to prison. The proportion of them who will still be in prison on any

one night is small; specifically it will consist of those persons sentenced less than x days ago to sentences of more than x days, for x being anything from one to 365. Departmental estimates in Victoria have placed this proportion at one in ten and this estimate is incorporated into the model. It would vary if courts either reduced or increased the skewedness of the distribution of shorter sentences. The accuracy of this figure for other jurisdictions can be tested by running the model for two or three years prior to the present day and checking the actual and 'predicted' numbers of prisoners with less than one year remaining to serve. If predicted numbers in this category increase too rapidly then the 1:10 proportion must be reduced to perhaps 1:12. Conversely if predicted numbers fall below actual counts then a 1:8 ratio may be more appropriate.

Security Classifications of Prisoners

The accommodation requirements of a prison are affected by the structure of the prison population. Prisoners of a violent and dangerous nature or those who are liable to escape cannot be kept in a low-security section of the prison, and conversely, trusted prisoners should not be placed in overly oppressive regimes. If the system of security classification is inflexible this can lead to empty beds in some sections while others are over-full. However, the borderlines between security classifications, no matter what system of classification is in operation, are relatively flexible and it could be argued that this makes it pointless to try to forecast prisoner numbers disaggregated by security groups. It is at least a good start to show forecast numbers disaggregated by time remaining to be served and perhaps by offence type, and the model has been constructed in such a way that this is possible. The proportion of the prison population in maximum, medium or minimum security classifications can be inferred from the proportions of long-term prisoners in the prison population and the proportions of non-violent offenders amongst receptions, or some such formula. Even so, it is of interest to see how the model can describe the application of current security classification practices, and how they might need to change in reaction to projected changes in the prison population.

Incorporating an algorithm for the allocation of prisoners to initial security classifications and then reallocating them, at intervals through their prison term, to successively lower security levels, as is the Victorian practice, involves effectively dividing the forecasting model into separate security streams. Victorian correctional practice is that prisoners serving more than one year are initially placed under maximum security on arrival, while those serving under one year go to medium security; all maximum security prisoners would then normally expect to be transferred to medium security after serving one-third of their term, and would go to minimum security after serving two-thirds. It is understood however that around one-third of prisoners fail to obtain the transfer at each stage. This has been interpreted to mean that:

- all prisoners serving more than one year remain in maximum security until they have served 1/3 time (including remissions);
- after 1/3 time, two-thirds of prisoners are allocated to medium and one-third remain in maximum security;
- after 2/3 time, 4/9 of prisoners are allocated to minimum, 4/9 to medium and 1/9 to maximum security.

Prisoners received to serve sentences of under one year are also divided 4:4:1 although, as before, only a fraction of them are retained at the end-of-year count.

Once again, similar sets of rules can be specified to represent classification systems operating in other jurisdictions. Incorporation into the model is normally simple. It is worth remarking, though, that the extra computational difficulties involved in projecting prisoner numbers by security classification may lead to a reduction in confidence in its results and may make it impossible to run the model on some small computers.

What to do About Remandees

The total prison population is usually augmented by remandees; that is, unconvicted persons awaiting trial or convicted persons awaiting sentence. To the extent that these persons eventually do not receive prison sentences, or if sent to prison do not have their time served on remand taken into account, their occupancy of prison accommodation is not covered by the model described so far.

It is perfectly arguable that, in fact, these persons should not be counted as prisoners since they are expected to be housed in special remand sections of the prison structures and may well have privileges not available to sentenced prisoners.¹⁴ If they are 'innocent until proven guilty' then they should not be treated like prisoners until at least proof of guilt has been legally established. In Victoria, steps were being taken to provide separate accommodation for remandees and it was therefore possible to ignore them in the projection of prisoner numbers. However, in some practical situations it is necessary to consider remandee accommodation, and although the methodology described to this point should not be used, similar techniques are available.

One could assume, for example, that the principal determinants of remand in custody decisions are the nature of the charge (e.g. seriousness, violence involved, etc.) and the prior record of the accused person, which might be expected, in turn, to be related to age and sex as well as offence-type. Table 3 shows some logical and consistent relationships covering age, sex, offence and previous contact with police: this in itself is not an adequate basis for projection but when linked with current remandee characteristics from the annual prison censuses would probably result in a credible sub-model for determining remandee

arrivals. Data on time served on remand, by offence-type, would then allow the estimation of remandees-on-hand figures. This type of formulation would then allow the input of modified assumptions, in particular, describing hypothetical toughening or easing of the judicial use of remand, or the effects of improved court efficiency upon remand durations.

The Treatment of Non-Custodial Corrections

Similar restrictions are placed on magistrates and judges with respect to non-custodial sentences to those regarding prison sentences; that is, there are limits to fines, maximum terms of probation, etc. and precedents have considerable power to define the appropriate range of penalty for a given offence. The data from Table 2 and Figure 6 can thereby be used to calculate likely numbers of offenders by type of non-custodial sentence. Average figures for fines could be obtained and applied to the forecast numbers of persons fined in order to forecast revenue from such sources, however, we are more interested in determining likely client numbers in programmes such as probation, attendance centres and community service orders.

The disposition matrix when applied to population forecasts gives us the number of receivals into such programmes each year, but the numbers on hand at any one time are dependent upon the sentence lengths handed down; for example, one probationer sentenced to two years occupies almost as much of a probation officer's time as three probationers each sentenced to eight months, although supervision is always more intensive at the start of any probation period. A method of extending the disposition matrix in these areas must be found, in the same way as prison terms are distributed according to recent statistics. Court statistics or corrections receival statistics should be available to construct a matrix similar to Table 5 and a simple methodology can be applied to then obtain numbers of clients by sentence length. From this can be calculated the likely trends in 'on-hand' figures from which the demand for departmental manpower and resources can be derived. Projection of probationer numbers should in fact be rather easier than the projection of prisoner numbers since terms of probation are generally set in whole numbers of years and are not subject to the uncertainties and quirks of a parole system. On the other hand, attendance centre and community service orders have a rather short history from which to project and entail durations usually counted in months rather than years which means that the numbers on hand at a given date will be a relatively low proportion of those received during the year. Community service orders in Victoria cannot be realistically projected at all because of their very recent commencement and uncertainty over the extent to which community service orders will replace the various other forms of sanction.

Table 5 gives the assumed sentence length distributions for both Probation and Attendance Centre Orders, by offence type, as derived from departmental records.¹⁵

PART II

THE OPERATIONAL LOGIC OF THE ORACLE MODEL

The Model's Ancestors

The choice of variables and structure of the relationships between them is vital in the determination of model structure. For example, in 1977 Flanagan¹⁶ wrote of linear multiple regression models for projecting prisoner numbers using population aged 20-29 years and court caseloads as the independent variables. Such models cannot be used to test hypotheses involving detailed interactions between external demographic, judicial and penal variables simply because they are subsumed into the main variables, that is they are assumed to be in fixed relationship to the main regression variables. For the same reason one cannot use simple growth rate extrapolation for long term projection although it has its uses in the very short term (say one to five years).¹⁷ Less elegant numerical methods allow rather more sophisticated assumptions to be built into the model.

Blumstein et al.¹⁸ defined the logical process underlying prisoner number projection as a five-step model using matrices of probabilities:

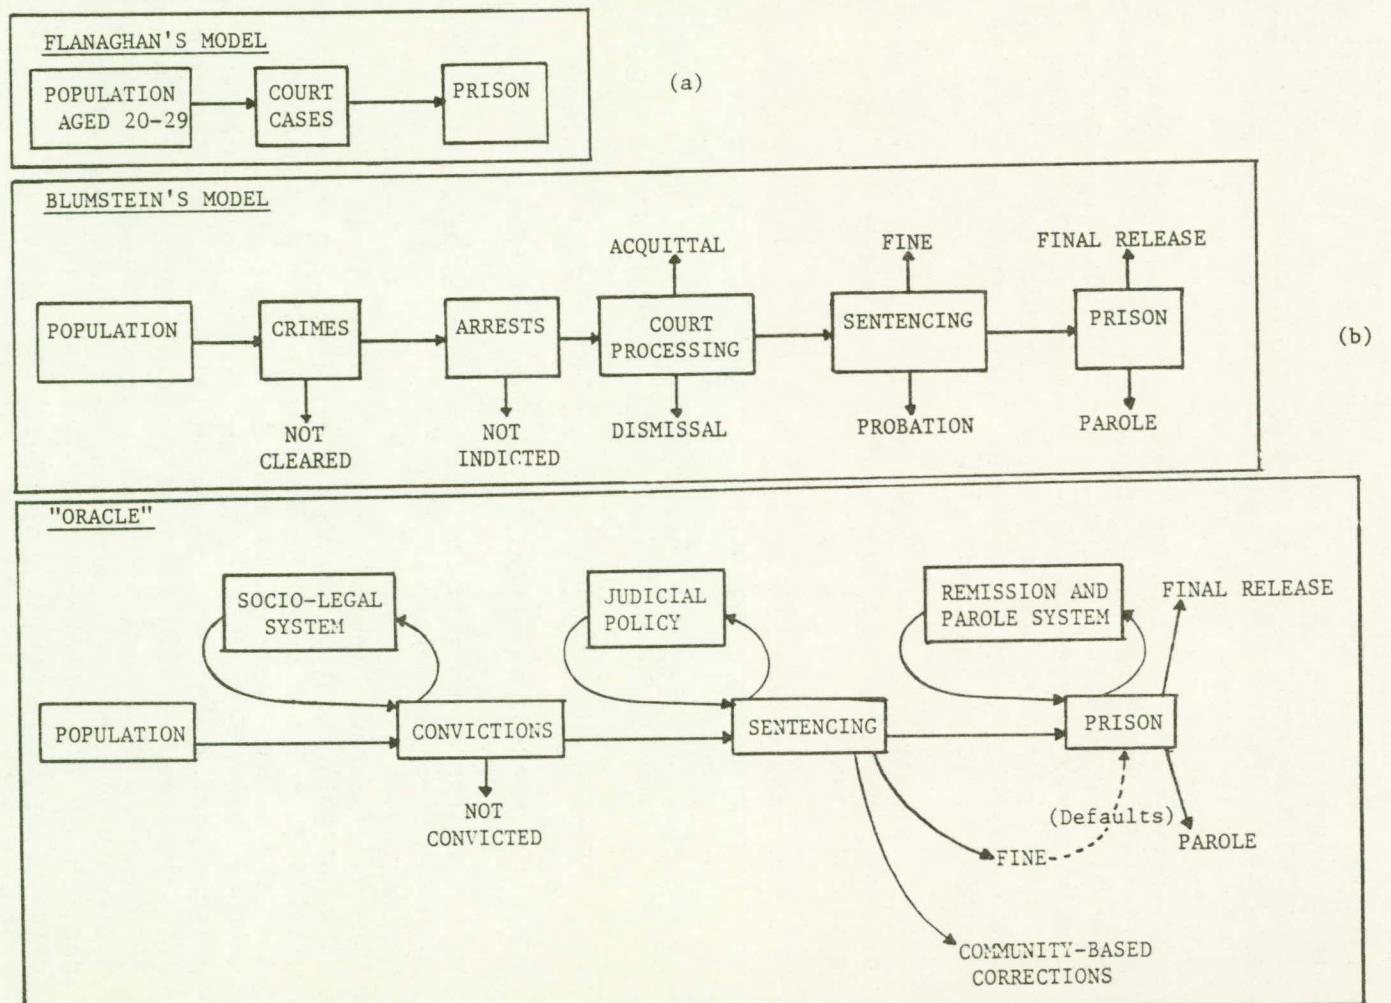

- the probability of an individual of a given age, race and sex committing a given offence type in a given year,
- the probability of such an individual being arrested,
- the probability of such an individual being charged,
- the probability of such an individual being convicted,
- the probability of such an individual being sentenced to imprisonment.

Figure 7 shows their schema. They further discussed the computational logic, whereby they model two separate streams of prisoners - those who were in prison at the beginning of the year and those who were received during the year. The model must somehow determine the reduction during the year of the initial prison population and the accumulation of new prison population from inmates received during the year. He makes some assumptions about the time served in prison using an exponential derived from Stollmack's¹⁹ earlier work, so that the reduction of the initial population is determined by the average time served for a given offence by a person of given age, race and sex. He also assumes that prisoners' arrivals are (poisson) randomly distributed throughout the year.

The model described below is similar in structure and mechanics but contains some major simplifications. Firstly, race is not considered as a demographic variable because in most parts of Australia the simple black/white dichotomy does not have the

Figure 7

CONCEPTUAL PROCESSES GENERATING PRISON POPULATIONS UNDER VARIOUS ASSUMPTIONS

relevance it does in the United States. This is not to forget that Aboriginal imprisonment rates in Australia are something over ten times the non-Aboriginal rate but the smallness of the numbers in most jurisdictions precludes separate analysis. Second, the probability of committing an offence, the probability of arrest, the probability of being charged and the probability of conviction are all subsumed into one matrix which is obtained from age/sex/offence specific conviction rates. Third, time served is calculated from recent actual statistics and norms rather than via an abstract mathematical assumption. These differences make this model rather less demanding of police and court data, which in Australia might be unavailable or incompatible with the corrections data, but do not basically change the form of the model. On the other hand this model goes further into the non-prison alternatives using similar techniques to the prisoner sub-model.

The Model's Mechanisms

Briefly, the model takes receivals from the court system during a year, adds them to the various corrections populations on hand at the beginning of the year and works out which of those persons will still be under correctional treatment at the end of the year. Figure 8 shows a flow-chart of the model.

The first stage, taking the projected population by age and sex and multiplying by the conviction rates, gives an estimate of the numbers of persons being sentenced by the courts by offence type, age and sex. These can be printed and checked against current figures and their validity assessed. Also, at this stage, detailed assumptions of future changes in rates of offending or conviction can be incorporated into the model by changing individual elements of the table of conviction rates.

Stage two takes the number of persons convicted and divides them according to the type of sentence, and, where appropriate, the duration of the sentence. This too is performed separately for each offence type so that detailed assumptions of changes in sentencing patterns can be incorporated by changing individual elements of the disposition rates table. The numbers of persons by disposition can also be printed for validity checking purposes.

Stage three calculates the minimum terms from the head sentences of prisoners received during the year, according to the percentages set out in Table 4. The elements of this table are manipulable to simulate potential changes in sentencing practice relating specifically to minimum terms. At this stage also the fine-defaulters are transferred into the prisoner numbers. The receivals are now added to the persons on hand at 30 June of the previous year.

The model next simulates the process of serving time within the system. Those on hand at the beginning of the year with less than one year to serve will of course have been released during the year, as will many of the receivals with sentences under one

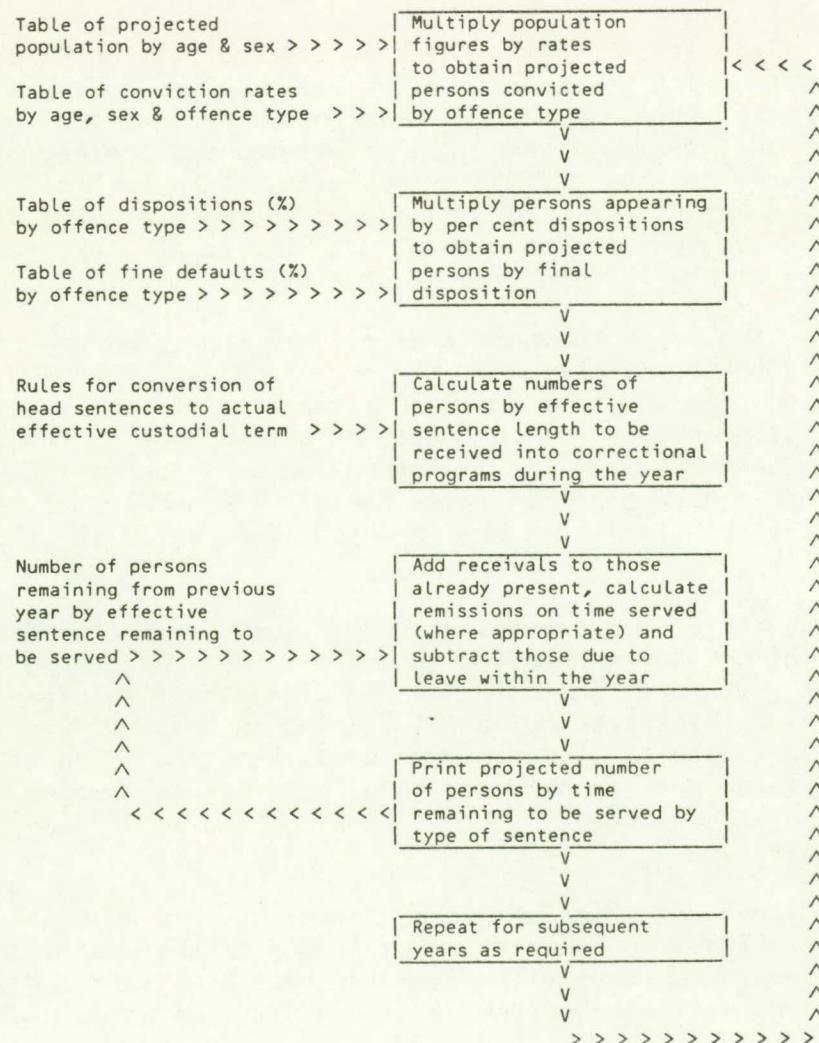

year. All others will have served one full year which will entitle them to a further six months' remission at the currently adopted rate. This one-for-two rate of remission is another part of the model's operation which can be modified to simulate possible administrative action.

Finally, the number of persons received during the year, by sentence type and sentence remaining to be served, and the number on hand at census date (30 June) are printed, and the cycle of the model begins again with updated population figures. At the end of the 18 year cycle which brings the model up to the year 2000, summary tables are produced, showing the trends in overall numbers received and on hand, by effective sentence remaining to be served and by type of sentence (that is, prison, probation, attendance centre).

The Fortran listing and the definitions of the variables used therein can be found in Appendices 1 and 2.

Figure 8

FLOW CHART FOR PROJECTION OF PRISONER NUMBERS 1982-2000

PART III

USE AND RESULTS OF THE MODEL

Obtaining a 'Base Run'

As with any area of forecasting, one can build into a corrections forecasting model the most ingenious representations of reality only to find that, when the model is called upon to produce results, it produces nonsense. The problems usually lie in the selection and balance of the variables and mechanisms used in the model, and the only way to test these aspects of the model is to feed in base data relating to a time gone by and run the model until it reaches the present day. The model's 'projections' should then be tested in every conceivable way against known actual statistics. For example, not only should total 'on-hand' prisoner numbers produced by the model be acceptably close to actual figures, but also the distributions, by offence type and sentence remaining to be served, of prisoners received during the year and prisoners on hand at the end of each year should be consistent with actual figures. If they do not tally, each intermediate output of the model (for example, numbers of persons proceeded against and numbers of sentenced persons by disposition) should be checked against known figures. Input data, if found suspect, must be modified; program steps, if leading to erroneous trends, must be changed. The model must be modified and re-run until two conditions are present:

- (1) the input data and mechanisms appear comprehensive and realistic to informed practitioners in the correctional administrative system; and
- (2) the results are acceptably close to known statistics in all respects.

The detail with which this process can be conducted depends considerably on the availability of past data, however, basic prisoner totals for all jurisdictions are available for several years back on a monthly basis and most jurisdictions conduct some sort of annual census of prisoners.²⁰ The National Prison Censuses of 1982 and 1983²¹ also provide a valuable common base with their crosstabulations by offence, aggregate sentence, time already served and actual expected sentence. Similar data can usually be obtained for non-custodial corrections from court statistics and from correctional management data. Also, the forthcoming National Census of Community Corrections (to take place on 30 June 1985) will provide useful background information in this area.

Testing of the Victorian data took the form of projecting from the June 1982 census 'prisoners on hand' data, along with non-custodial figures relating to the same period, and checking all stages of the model against known 1983 data. Key items included in the checks were actual numbers received during the year by age and sex, by offence, and by sentence type (for example, prison, probation, attendance centre) and length. Court

statistics were used wherever prison data were inadequate or unavailable. Some elements of the conviction rates and disposition rates matrices were modified to reflect recent trends in receivals of particular offence types and ages of offenders. Prison census data from June 1983 and the results of non-custodial censuses were then used to confirm the accuracy of the mechanisms dealing with persons remaining in the corrections system throughout the year and persons being released. When satisfactory results were obtained the model was then allowed to run for the full projection period, that is up to the year 2000. At this stage the population projections used were the 'most likely' projections as described in Preliminary Population Projections,²² and all model options were set at 'status quo'. In other words the base run can be described as a projection of likely prisoner numbers under 'no change' conditions. Prison administrators normally have some idea of their expectations under such conditions and it is valuable again at this stage to see if the model's results conform to those expectations. If they do not conform, it does not necessarily prove the projections false, but it is necessary to pinpoint the basic area of disagreement and adjudicate - the model must be sufficiently robust to convince informed skeptics of its accuracy at this stage - and modify the model if necessary.

In the Victorian case, the model forecast an annual prisoner intake of 6252 rising to 6817 in the year 2000. These figures were commensurate with current departmental estimates and expectations. When sentence lengths, paroles and remissions were taken into account, the June 1982 figure of 1753 persons on hand is projected to rise rapidly through 2000 persons within two years and then slow to reach 2300 by 1990 and a figure of 2520 in the year 2000. A significant feature of this projected rise of around 800 persons in 18 years is that half of these additional persons would be prisoners with more than two years remaining to serve. This is partly the result of greater numbers of receivals but partly also the result of the slow accretion of long-term prisoners. These would be generally older, often the more violent offenders, and inevitably more institutionalised than the majority of prisoners with under two years to serve. This, on reflection, was a trend quite in conformity with departmental expectations, and indeed fears, and so these figures were accepted as a base scenario against which other runs, incorporating different assumptions, could be compared.

Other parts of the model, such as the probation and attendance centre forecasts also tallied with current numbers and expectations. A fairly significant jump from 3000 to 3850 on probation and a near doubling of attendance centre clients on hand in June 1983 accorded with actual figures. (See Appendix 4 for the printed results of the Base Run.)

Initial Variations on the Base Run

Having arrived at an acceptable base run, a number of scenarios which might be envisaged in the future should be

obtained from departmental staff, and simulated in the model using those variable features in the model as described above. Each of the subsequent set of runs should generally comprise one set of variations from the base run. Clearly many sets of variations, some at odds with others, can be operating simultaneously in the real future world, but, at least initially, their combined results can be inferred from comparisons of the results of the individual runs.

These initial variants of the base run principally serve the twin purposes of further testing the logic of the model (for example, showing that events likely to add to the prison population actually do so in the model, and vice versa) and showing the sensitivity of the model to the assumptions being modelled. In most cases, the incorporation of the assumption into the model should be a simple matter of activating three or four lines in the computer program. Table 6 shows the nature of the assumption tested in each Victorian run, and Figure 9 shows the projected trends in prisoner numbers at 30 June each year for the base run and each of the sensitivity runs.

Generally it would appear from the detailed printouts (see Appendix 4) that although the growth in numbers of long-term prisoners accounts for much of the increases common to all curves in Figure 9, it is the large number of short-sentence prisoners which can best be manipulated to influence total prisoner numbers.

The inclusion of the population trends in Figure 9 also highlights the fact that all these prisoner number projections resulting from the sensitivity runs forecast increasing per capita imprisonment rates until the mid 1990s at least, whichever population projection is used. (The scales on the graph are drawn so that wherever the prisoner number curve is above the selected population curve the per capita imprisonment rate is higher than that of the base year, that is, 1982.) Hence we have immediate support for the adoption of a range of policies if prisoner numbers or the overall per capita imprisonment rates are to be kept down since none of the policies tested appear capable of doing so alone.

The results show that the most effective way to reduce prisoner numbers is seen in Run 4 which incorporates a 50 per cent transfer of persons sentenced to under six months' imprisonment to some form of non-custodial option. Although these prisoners do not occupy cells for very long their sheer numbers are significant, and since the time spent by staff in preparing files, and attending to their reception, installation and discharge is almost the same for them as for much longer term prisoners, they are a considerable burden on the prison system. Almost certainly, however, it would require complex legislative changes to achieve such a shift in sentencing emphasis, and partial success would logically only achieve a part of the reduction in prisoner numbers shown in the graph.

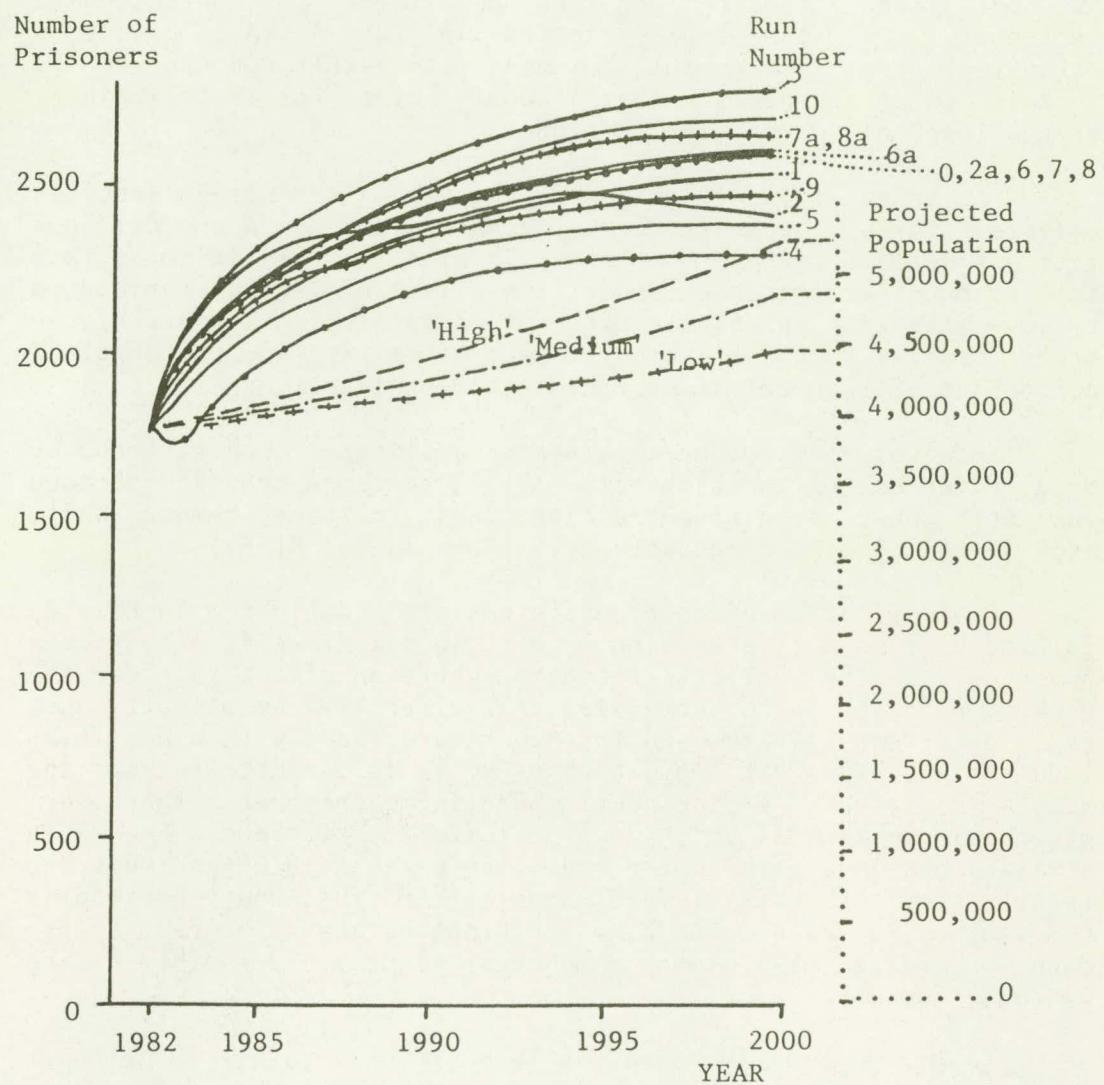

Almost as effective in reducing prisoner numbers is a

Table 6
SENSITIVITY ANALYSES ASSUMPTIONS TESTED

Run Number	Nature of Assumptions Tested
0	Base Run - medium population trend, with status quo criminal justice system.
1	As Base Run, but 50% of those presently sent to prison for fine-default are transferred to non-custodial.
2	As Base Run, but increased court activity (to reduce current backlog) results in 8.5% more cases heard in 1983, 7.5% in 1984... (reducing to) 0.5% more in 1991, and then reducing further so that by year 2000 there are 8.5% fewer cases than 'expected'. Caseloads are modified 'across the board', that is, all offence types, dispositions, etc.
2a	As Run 2, but the number of cases resumes 'base' trend after 1991.
3	As Base Run, but longer sentences for those sentenced to under 1 year (or less generous remissions) result in 25% increase in those remaining at end of year.
4	As Base Run, but 50% of those presently sentenced to under 6 months imprisonment given non-custodial sentences (distributed as per similar offences where non-custodial sentences are served).
5	As Base Run, but 50% of those serving 3 years or more are released during their penultimate year in pre-release program.
6	As Base Run, but juvenile unemployment causes 8.5% increase in juvenile (age 16-19) offending in Robbery, Burglary, Theft, Property Damage, Prostitution and Good Order in 1983, declining to 0.5% increase in 1991, and resuming 'base' trend thereafter.
6a	As Run 6, but 8.5% constant increase through entire period 1983-2000.
7	As Base Run, but 8.5% (declining to 1991 in similar manner to Run 6) increase in white collar crimes of Fraud and Drug Offences by persons aged over 19.
7a	As Run 7, but 8.5% constant increase.
8	As Base Run, but 8.5% (declining to 1991 in similar manner to Run 6) increase in Traffic Offences.
8a	As Run 8, but 8.5% constant increase.
9	As Base Run, but using low rate of population growth.
10	As Base Run, but using high rate of population growth.

Figure 9

PROJECTED PRISONERS ON HAND IN VICTORIA AT 30 JUNE 1982-2000
FROM SENSITIVITY ANALYSIS RUNS AND TOTAL POPULATION
TRENDS FOR THE SAME PERIOD

Note:

1. See Table 6 for details of Run numbers and characteristics.
2. The dashed lines in the graph are the High, Medium and Low population projection curves, shown in order to demonstrate changes in imprisonment rates relative to the base year 1982. (Whenever the prisoner number curve is higher (or lower) than the population curve the imprisonment rate is higher (or lower) than that of 1982.)

reduction in time actually served in prison by longer term prisoners (Run 5). This could in fact be achieved by an overall reduction in head sentences, by increasing the maximum remission ratio from one-third of minimum term to two-fifths or even a half, or by a form of pre-release as now operates in some states. Again, the reduction in numbers achievable by these methods would depend upon the percentage reduction in average times served.

A third policy which leads to reduced prisoner numbers is a 50 per cent transfer of fine defaulters to non-custodial sentences. At the degree tested in Run 1 this policy is relatively less successful however than either Run 4 or Run 5. This is not to say however that it would not be easier to achieve, at the level of 50 per cent or higher.

As one would expect, hypothesised increases in specific offences largely committed by juveniles (Runs 6 and 6a) have little effect on prisoner numbers. This, of course, fails to take into account the possible longer term effect of serious recidivism by juveniles with relatively minor prior convictions, however, one could specify such a scenario and test it in the model if appropriate parameter values could be identified.

However, low volume/long sentence offences such as fraud or drug offences or the high volume/short sentence traffic offences can both make significant differences to prisoner numbers while high levels of offending continue. (Runs 7, 7a, 8, 8a)

The effects of court decisions are highlighted in Runs 2, 2a and 3. Run 2 is something of a straw man since it effectively hypothesises the unlikely situation where an effort to clear the backlog of cases is so successful that after 1991 it actually acts as a deterrent to crime and the courts are faced with a declining level of activity. It does, however serve to demonstrate that the model is capable of forecasting declining prisoner numbers when given circumstances which would foster that trend. Run 2a is similar, but is a rather more realistic version in which the trend reverts to the base levels soon after the court backlog is removed. Run 2a and Run 3, which hypothesises a judicial crackdown on relatively minor offenders, show very rapidly rising prisoner numbers.

Runs 9 and 10 show the level of uncertainty in prisoner numbers directly arising from uncertainty in forecasting trends in the general population. They effectively form upper and lower bounds to the Base Run which uses an intermediate population trend. Similar bounds could be determined around each of the other trend curves to establish limits to planning error potentially due to the least controllable factor in the simulation, that is, population.

The model also produces projected non-custodial numbers for each of these scenarios, which should be scrutinised in as much detail as the prisoner number results. The trends in non-custodial numbers clearly depend upon the assumptions made in the sensitivity runs and these results should also be compatible with

reasonable expectations given the nature of the assumptions made. Suffice it to say here that, in the Victorian case, this was indeed the case but it is judged unnecessary to relate them here. It is of much greater interest to move on to the final phase of the model's use and present the more detailed non-custodial results there.

Selected Scenarios

Up to this stage, we have regarded our base run as a benchmark against which we have tested certain hypothesised policy changes and exogenous changes. Now we turn to a more considered approach to likely future trends.

Certain combinations of circumstances are of particular interest to forecasters. For example, one can talk of the 'most likely' set of circumstances, the best (or worst) likely set, or the best (or worst) possible set of circumstances. Likewise one can talk of a 'do nothing' set of circumstances or a 'do everything' set. Each of these concepts can be described as a scenario. This section describes the results of three scenarios and compares them with the base-run results which may be regarded as a 'do nothing' scenario.

Clearly there is an intuitive ranking of the scenarios mentioned above. From most adverse to most favourable they are: 'worst possible', 'worst likely', 'most likely', 'best likely' and 'best possible', with 'do nothing' and 'do everything' at indeterminate points along that scale. The concepts of worst possible and best possible incorporate effectively unforeseeable events such as unprecedeted reductions or increases in rates of offending. No forecaster should be expected to manage that magnitude of change, and it is therefore reasonable to restrict ourselves to the more likely sets of circumstances.

On best available advice, three sets of circumstances should be constructed:

- (a) a best likely, or optimistic scenario. The Victorian example below foresees low rates of population growth, a 50 per cent pre-release program, and a 50 per cent transfer to non-custodial sentences of those previously sentenced to under six months, and those previously jailed for fine defaults (that is, Sensitivity Runs 1, 4, 5 and 9).
- (b) a most likely run, based on current expectations. In Victoria this was defined as longer sentences for those serving less than one year, but a 50 per cent pre-release program, and a 50 per cent transfer to non-custodial sentences of those previously sentenced to under six months and those previously gaoled for fine defaults (that is, Sensitivity Runs 1, 3, 4 and 5).

(c) a worst likely, or pessimistic scenario. The Victorian example foresees high rates of population growth, continuing high rates of crime in specific juvenile areas, white collar offences and traffic offences, and longer sentences for those sentenced to under one year, with only the one alleviating policy of reducing by 50 per cent the number of imprisoned fine defaulters (that is, Sensitivity Runs 1, 3, 6a, 7a, 8a and 10).

Figure 10 and Table 7 show the results of these three scenarios along with the original base run which can be regarded as a 'no change' scenario. In these scenarios, the pre-release program commences in 1983-84, other forms of diversionary schemes commence in 1984-85, while other changes (for example, to rates of conviction, population levels or sentence lengths) take immediate effect.

Perhaps the most striking feature of Figure 10 is that, under relatively favourable conditions, the per capita imprisonment rate can be retained at Victoria's customarily low level. The prisoner number curves for both the 'most likely' and 'optimistic' runs stay close to their respective population curves (that is, the Medium and Low projection).

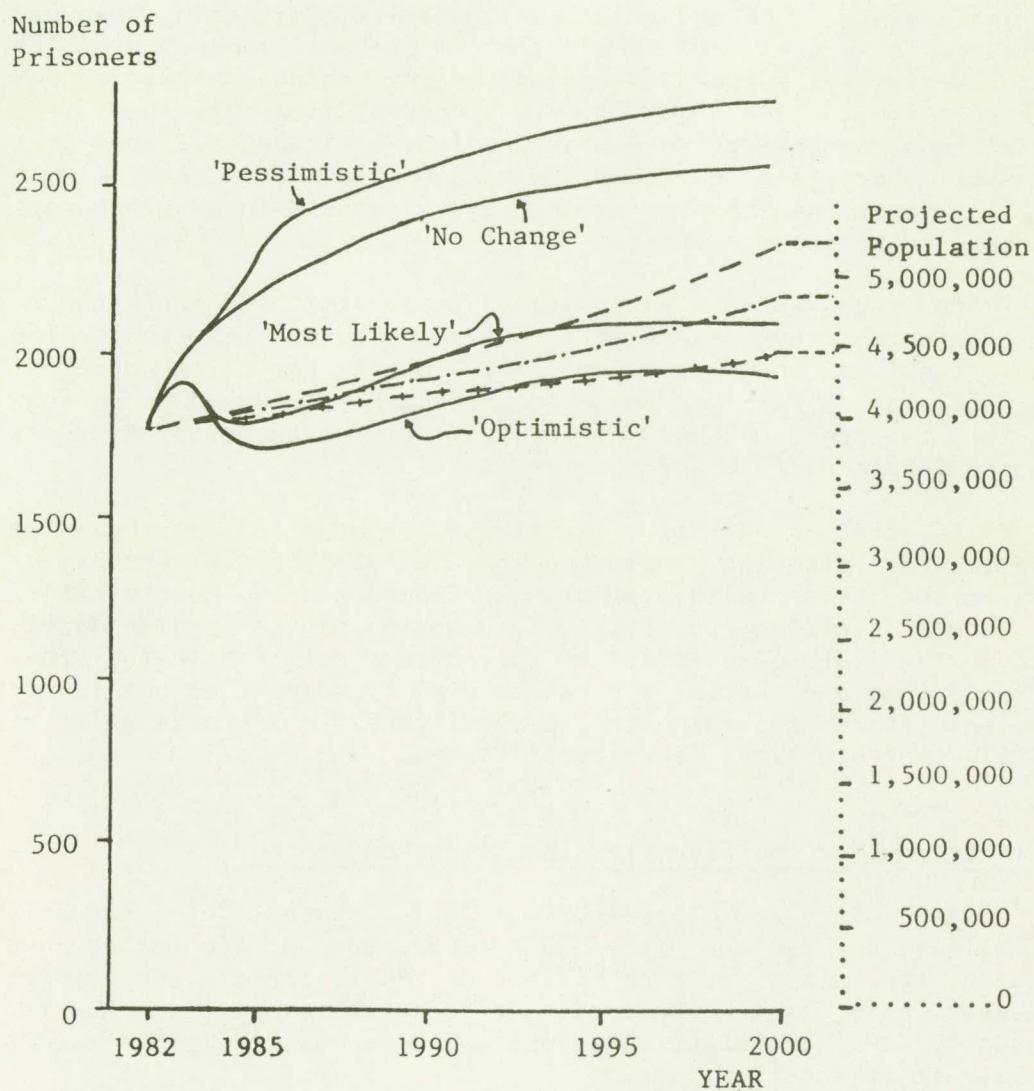

Table 7

PROJECTED PRISONERS ON HAND IN VICTORIA AT 30 JUNE 1982-2000:
SELECTED SCENARIOS

Year	Number of Prisoners by Scenario Type			
	No Change	Pessimistic	Most Likely	Optimistic
1982	1753	1753	1753	1753
1983	1963	1917	1835	1729
1984	2061	2017	1677	1575

2000	2566	2851	2121	1937

Figure 10

PROJECTED PRISONERS ON HAND IN VICTORIA AT 30 JUNE 1982-2000
FROM SELECTED SCENARIO RUNS AND TOTAL POPULATION TRENDS
FOR THE SAME PERIOD

Note: The dashed lines in the graph are the High, Medium and Low population projection curves, shown in order to demonstrate changes in imprisonment rates relative to the base year 1982. (Whenever the prisoner number curve is higher (or lower) than the population curve the imprisonment rate is higher (or lower) than that of 1982.)

The policy of imposing non-custodial sentences on fine defaulters shows an immediate and persistent fall in prisoner numbers of around 150 prisoners. The hypothesised toughening of short-term sentences (Sensitivity Run 3) has a marked upwards push on prisoner numbers, however it can be more than compensated by the adoption of the 50 per cent pre-release program and the greater use of non-custodial options (Sensitivity Runs 4 and 5). If, additionally, population growth is at the lower end of the officially accepted projections, then even lower prisoner numbers are attainable. Even this most optimistic scenario, however, envisages a growth of 10 per cent in prisoner numbers over the next twenty years despite major policy changes towards non-incarceration. The most likely scenario, incorporating a less marked tendency towards non-incarceration, envisages a 20 per cent increase over this period. The most pessimistic scenario, with only a token non-incarceration policy, results in a 50 per cent increase in prisoner numbers.

On a present day per prisoner cost of \$21,750 per annum,²³ the projected savings on prison expenditures between the 'no change' policy and the 'most likely' policy are of the order of nine million dollars per annum, although not all would be savings to the taxpayer because of the costs of the supervision orders imposed in place of the prison terms.

Selected scenarios like these should form the basis of departmental planning including the provision of new prisons, or new accommodation within existing prisons, and the determination of future staffing levels. They would inevitably also highly colour the future selection of corrections policies in the areas of remissions and parole, and can be used to support arguments put to legislators regarding the appropriateness and practicality of certain sentence types for given offences.

Implications for the Security Classification System

As discussed previously, any system of security classification can be flexible enough around the borderlines between the classification levels so that forecasting becomes somewhat pointless. However, it is interesting to see how the presently defined classifications would be changed by the trends in overall prisoner numbers.

The Victorian base run was re-worked using the security classifications algorithm and produced the results shown in Figures 11 and 12 and Table 8. The increased complexity of the model and its compounding of rounding errors produce prisoner numbers slightly different from the original base run, eventually amounting to a difference of 37 (or 1.4 per cent) in the final projected year of the run. However, it confirmed the increasing share of higher security prisoners which one would probably infer from the increasing shares of long-term prisoners.

As Figure 11 shows, the recent growth in numbers of long-term prisoners continues to swell the numbers and proportion of

maximum security prisoners, with the pattern repeated later in medium security as they filter through the system. In both absolute terms and in percentages, however, the number of minimum security prisoners reduces as sentencing practices continue to divert minor offenders to non-custodial sentences. The initial split of 40 per cent in maximum, 40 per cent in medium and 20 per cent in minimum security is fairly quickly changed to one of around 45:45:10 if current allocation practices are retained. This suggests perhaps that better identification of low risk prisoners may be required under a regime in which long-term prisoners are more predominant, if per prisoner costs are to be kept to levels commensurate with present day costs, since high security prisoners necessarily require more resources and supervision than those at lower levels.

Other scenarios could be tested through this version of the model but have not been documented here, since they produce fairly predictable deviations from the Base Run given our knowledge of overall prisoner numbers trends in each scenario.

PERCENTAGE SHARES BY SECURITY CLASSIFICATION - BASE RUN

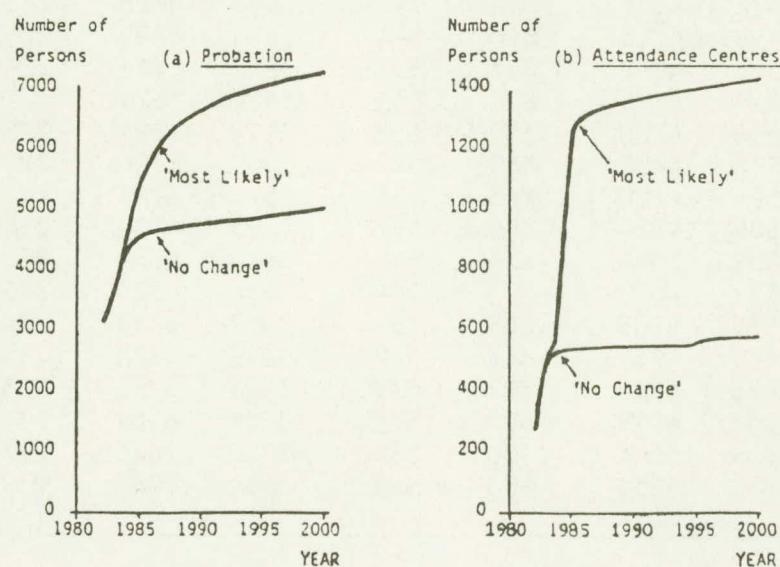

Non-Custodial Options for Adult Offenders

Of far more interest, particularly because of the cost implications, are the effects of the various scenarios on non-custodial client numbers, in particular the Probation system and the recently instituted Attendance Centres and Community Service Order Schemes. The results of the model are presented in Table 9 and Figure 13. Two runs of the model were made, using the 'no change' scenario and the 'most likely' scenario. The changes in sentencing practices implicit in the 'most likely' scenario produce significant increases in the workloads of the two non-custodial programmes. The detailed assumptions made are as follows:

- the 50 per cent of fine defaulters are transferred to attendance centres where they receive sentence lengths distributed according to offence type, as if they had been originally sentenced to attendance centres.
- the 50 per cent of those previously sentenced to under 6 months imprisonment are transferred equally to probation and attendance centres, according to their offence type, and given sentence lengths distributed as if they had originally been sentenced that type of disposition.

Figure 13

PROJECTED NUMBER OF PERSONS SERVING NON-CUSTODIAL SENTENCES IN VICTORIA AT 30 JUNE 1982-2000

Because the attendance centre option is of such recent origin it would be expected that a clientele would be building up rapidly, as in fact departmental records show over the past few years. The percentages of offenders sentenced to attendance centres have been increasing, and in consequence, so has the number of receptions. The considerable excess of receptions over completions accounts for the projected growth in 1982-83, and the assumption of stability in these disposition rates, coupled with the short periods served, explains the flattening out of the curves. With the longer sentences, probation shows a steadier climb, except where the policy changes occur.

PART IV

CONCLUSION

It is hoped that this model, and the description of it in this monograph, is sufficiently simple to be understood and used, yet at the same time sufficiently comprehensive in its approach and flexible in its requirements, to enable any interested corrections department to adapt it to its own circumstances.

The computer program listed in Appendices 1 and 2 is written in very simple FORTRAN for the Cyber 76 and Cyber 835 Computer systems operated by the Commonwealth Scientific and Industrial Research Organisation (CSIRO) in Canberra. It is therefore readily available by arrangement with CSIRO and the Australian Institute of Criminology for use by government departments, through CSIRO terminals which are located in all major cities of Australia. It can be modified to suit any Fortran compiler, could be translated into Basic, and could in fact, in its present form, be run on many of the relatively modest personal computers which are available to small research offices. It could, with a little help from a competent programmer, be made fully conversational, so that for example, an administrator with little or no computer experience can be prompted by the computer program and asked to specify the values of input data required or select the precise nature of the assumptions to be made from a list of options displayed on the screen.

The sources of data have been discussed - The Australian Bureau of Statistics, the Police, the Courts and the Corrections Departments' own records. Some degree of imagination is sometimes necessary to complete the data requirements and where actual data are not available estimates have to be made. But even here, in using the model in Victoria, cross-checking of model outputs has always appeared successful in identifying bad data or implausible assumptions.

The model can be useful to practitioners throughout the criminal justice field - police, courts, legislators, prison administrators and probation or parole officers. Probably it is at its most useful when used simultaneously by all of these groups, each ensuring that their own particular items of data and assumptions are correct and adequate. This form of joint monitoring of system options often leads surreptitiously to an integrated approach to data collection in the justice system, which in itself is a worthwhile objective to the extent that it enables real evaluation of the operation of the system in action.

The problem of forecasting still remains, however. Forecasting models are not all-seeing crystal balls and can only mechanically work through the implications of the scenarios envisaged by the users of the model. Much depends on the imagination and interpreting powers of the user. However, as an aid to the imaginative user, this model should (I predict) be a powerful tool. Only time can really tell if I am correct!

C      CENTRE TREATNERS THROUGH THE SYSTEM, IN THREE-MONTHLY
C      COHORTS - THIS IS NECESSARY BECAUSE OF THE RELATIVELY
C      SHORT PERIODS THEY SERVE.  THE STRANGE-LOOKING DECIMALS
C      ARE THE RESULT OF ASSUMING THAT RECEIVALS TO ATTENDANCE CENTRES
C      ARRIVE EVENLY THROUGHOUT THE YEAR SO THAT FOR EXAMPLE THE NUMBER
C      ON HAND WITH UNDER 3 MONTHS TO SERVE IS MADE UP OF SOME OF THOSE
C      OF THE LAST QUARTER'S RECEIVALS SENTENCED TO LESS THAN 3 MONTHS
C      PLUS SOME OF THOSE SENTENCED EARLIER TO LONGER TERMS WHO HAVE SERVED
C      ALL BUT 3 MONTHS OF THEIR SENTENCE
C

(ii) The program incorporating prisoner classifications

P,PS000.
COMMENT THIS PROGRAM DOES NOT PROTECT NON-CUSTODIAL NUMBERS
BEYOND THE DISPOSITION MATRIX STAGE NOR DOES IT INCORPORATE
SENSITIVITY OPTIONS. THE METHODOLOGY IS RATHER
DIFFERENT FROM THAT OF THE STANDARD MODEL: EACH COHORT OF RECEIVALS
HAS ITS PRISON CAREER, INCLUDING PROGRESS THROUGH REMISSIONS AND
THROUGH THE SECURITY CLASSIFICATIONS, MAPPED OUT AS THEY "ARRIVE".
SURVIVORS OF SUCCESSIVE COHORTS ARE THEN SUMMED TO OBTAIN EACH
YEARS ON-HAND FIGURES BY TIME REMAINING TO BE SERVED AND BY SECURITY
CLASS.
